A finite tree is a finite partially ordered set

\[ \mathcal{B} = (B, \leq) \]

such that:

(i) \( B \) has a smallest element (called the root of \( \mathcal{B} \));

(ii) for each \( s \in B \) the set \( \{ t \in B : t \leq s \} \) is a totally ordered subset of \( B \).
A finite tree is a finite partially ordered set

\[ B = (B, \leq) \]

such that:

(i) \( B \) has a smallest element (called the root of \( B \));
(ii) for each \( s \in B \) the set \( \{t \in B : t \leq s\} \) is a totally ordered subset of \( B \).

For finite trees \( B_1 \) and \( B_2 \), an embedding of \( B_1 \) into \( B_2 \) is a one-to-one mapping

\[ f : B_1 \rightarrow B_2 \]

such that

\[ f(a \land b) = f(a) \land f(b) \]

for all \( a, b \in B_1 \), where \( a \land b \) denotes the infimum of \( a \) and \( b \).
• **Kruskal’s Theorem.** For every infinite sequence of trees \( (B_k : k < \omega) \), there exist \( i \) and \( j \) such that \( i < j < \omega \) and \( B_i \) is embeddable into \( B_j \).

(In particular, there is no infinite set of pairwise nonembeddable trees.)
• **Kruskal’s Theorem.** For every infinite sequence of trees \((B_k : k < \omega)\), there exist \(i\) and \(j\) such that \(i < j < \omega\) and \(B_i\) is embeddable into \(B_j\).
(In particular, there is no infinite set of pairwise nonembeddable trees.)

• **Theorem** (H. Friedman, D. Schmidt) Kruskal’s Theorem is not provable in \(\text{ATR}_0\).
• **Kruskal’s Theorem.** For every infinite sequence of trees \((B_k : k < \omega)\), there exist \(i\) and \(j\) such that \(i < j < \omega\) and \(B_i\) is embeddable into \(B_j\).

(In particular, there is no infinite set of pairwise nonembeddable trees.)

• **Theorem** (H. Friedman, D. Schmidt) Kruskal’s Theorem is not provable in \(\text{ATR}_0\).

• The proof utilizes that Kruskal’s Theorem implies that \(\Gamma_0\) is well-founded.
The Extended Kruskal Theorem

For $n < \omega$, let $\mathcal{B}_n$ be the set of all finite trees with labels from $n$, i.e. $(\mathcal{B}, \ell) \in \mathcal{B}_n$ if $\mathcal{B}$ is a finite tree and

$$\ell : B \rightarrow \{0, \ldots, n - 1\}.$$ 

The set $\mathcal{B}_n$ is quasiordered by putting $(\mathcal{B}_1, \ell_1) \leq (\mathcal{B}_2, \ell_2)$ if there exists an embedding

$$f : \mathcal{B}_1 \rightarrow \mathcal{B}_2$$

such that:

- $\ell_1(b) = \ell_2(f(b))$ for each $b \in \mathcal{B}_1$;
- if $b$ is an immediate successor of $a \in \mathcal{B}_1$, then for each $c \in \mathcal{B}_2$ in the interval $f(a) < c < f(b)$, $\ell_2(c) \geq \ell_2(f(b))$. 

This condition is called a gap condition.
The Extended Kruskal Theorem

- For $n < \omega$, let $B_n$ be the set of all finite trees with labels from $n$, i.e. $(B, \ell) \in B_n$ if $B$ is a finite tree and

$$\ell : B \to \{0, \ldots, n - 1\}.$$ 

The set $B_n$ is quasiordered by putting $(B_1, \ell_1) \leq (B_2, \ell_2)$ if there exists an embedding

$$f : B_1 \to B_2$$ such that:

- $\ell_1(b) = \ell_2(f(b))$ for each $b \in B_1$;
The Extended Kruskal Theorem

For $n < \omega$, let $\mathcal{B}_n$ be the set of all finite trees with labels from $n$, i.e. $(\mathcal{B}, \ell) \in \mathcal{B}_n$ if $\mathcal{B}$ is a finite tree and

$$\ell : B \to \{0, \ldots, n-1\}.$$

The set $\mathcal{B}_n$ is quasiordered by putting $(\mathcal{B}_1, \ell_1) \leq (\mathcal{B}_2, \ell_2)$ if there exists an embedding

$$f : \mathcal{B}_1 \to \mathcal{B}_2$$

such that:

- $\ell_1(b) = \ell_2(f(b))$ for each $b \in B_1$;
- if $b$ is an immediate successor of $a \in B_1$, then for each $c \in B_2$ in the interval $f(a) < c < f(b)$,

$$\ell_2(c) \geq \ell_2(f(b)).$$

This condition is called a gap condition.
The Extended Kruskal Theorem

**Theorem.** (Friedman) For each $n < \omega$, $\mathcal{B}_n$ is a well quasi ordering (abbreviated $\text{WQO}(\mathcal{B}_n)$), i.e. there is no infinite set of pairwise nonembeddable trees.
**The Extended Kruskal Theorem**

**Theorem.** (Friedman) For each $n < \omega$, $B_n$ is a well quasi ordering (abbreviated $WQO(B_n)$), i.e. there is no infinite set of pairwise nonembeddable trees.

**Theorem** $\forall n < \omega \ WQO(B_n)$ is not provable in $\Pi^1_1 - \text{CA}_0$. 
The Extended Kruskal Theorem

**Theorem.** (Friedman) For each $n < \omega$, $\mathcal{B}_n$ is a well quasi ordering (abbreviated $\text{WQO}(\mathcal{B}_n)$), i.e. there is no infinite set of pairwise nonembeddable trees.

**Theorem** $\forall n < \omega \ WQO(\mathcal{B}_n)$ is not provable in $\Pi^1_1 – \text{CA}_0$.

- The proof employs an ordinal representation system for the proof-theoretic ordinal of $\Pi^1_1 – \text{CA}_0$. The ordinal is $\psi_0(\Omega_\omega)$.

  - **GMT** is not provable in **Π** 1 – **CA** 0.
Ockham’s Razor
In what follows, we shall be solely dealing with classical logic. Therefore we can simplify the sequent calculus as follows:

- We get rid of the **structural rules** by using **sets of formulae** rather than **sequents of formulae**. This has the effect that **exchange** and **contraction** happen automatically:

\[
\{ C_1, \ldots, C_r, A, A, D_1, \ldots, D_s \} = \{ D_1, \ldots, D_s, A, C_1, \ldots, C_r \}
\]

We take care of **weakening** by adding all the formulae we may be interested in from the start; thus we have more liberal axioms:

\[ A, \Gamma \Rightarrow \Delta, A \]
Using the **De Morgan laws** of classical logic we can push **negations** in front of **atomic** formulae. Also, in classical logic $\neg, \land, \lor$ forms a **complete** set of connectives. Thus we can simplify matters, by demanding that formulae are built up from atomic and **negated atomic formulae** (literals) by means of $\land, \lor, \forall, \exists$.

**Negating** a formula $A$ then becomes a defined operation:

- $\neg\neg A := A$ if $A$ is atomic;
- $\neg(A \land B) = \neg A \lor \neg B$; $\neg(A \lor B) = \neg A \land \neg B$;
- $\neg\forall x F(x) := \exists x \neg F(x)$; $\neg\exists x F(x) := \forall x \neg F(x)$.

In classical logic we don’t need the two sides of a sequent

$$A_1, \ldots, A_r \Rightarrow \Delta$$

since it can be re-written as

$$\Rightarrow \neg A_1, \ldots, \neg A_r, \Delta$$
In the Tait-style version of the **classical sequent calculus** \( \Gamma, \Delta, \Lambda, \Theta, \ldots \) range over finite sets of formulae in **negation normal form**. \( \Gamma, \Delta \) stands for \( \Gamma \cup \Delta \) and \( \Delta, A \) is short for \( \Delta \cup \{A\} \).
The **inferences** of the **Tait-calculus** are as follows:

(Axiom) $\Gamma, A, \neg A$

($\land$) \[
\begin{array}{c}
\Gamma, A \\
\Gamma, A' \\
\end{array} \rightarrow 
\begin{array}{c}
\Gamma, A \land A' \\
\end{array}
\]

($\lor$) \[
\begin{array}{c}
\Gamma, A_i \\
\end{array} \rightarrow 
\begin{array}{c}
\Gamma, A_0 \lor A_1 \\
\end{array} \text{ if } i = 0 \text{ or } i = 1
\]

($\forall$) \[
\begin{array}{c}
\Gamma, F(a) \\
\end{array} \rightarrow 
\begin{array}{c}
\Gamma, \forall x F(x) \\
\end{array}
\]

($\exists$) \[
\begin{array}{c}
\Gamma, F(t) \\
\end{array} \rightarrow 
\begin{array}{c}
\Gamma, \exists x F(x) \\
\end{array}
\]

(Cut) \[
\begin{array}{c}
\Gamma, A \\
\Gamma, \neg A \\
\end{array} \rightarrow 
\begin{array}{c}
\Gamma \\
\end{array}
\]

Of course, the variable $a$ in ($\forall$) is an eigenvariable.
Part II: Predicative Proof Theory
These are theories for Gödel's notion of constructibility restricted to sets of natural numbers. Use ordinal indexed variables $X_\alpha$, $Y_\alpha$, $Z_\alpha$, ...

1. Level 0 variables range over sets definable by numerical quantification.
2. Level $\alpha > 0$ variables range over sets definable by numerical quantification and level $< \alpha$ quantification.

Impredicative Proof Theory

Impredicative Definitions: Poincaré, Russell, Weyl

• An impredicative definition of an object refers to a presumed totality of which the object being defined is itself to be a member.

• Example: to define a set of natural numbers $X$ as $X = \{ n \in \mathbb{N} : \forall Y \subseteq \mathbb{N} F(n, Y) \}$ is impredicative since it involves the quantified variable '$Y' ranging over arbitrary subsets of the natural numbers $\mathbb{N}$, of which the set $X$ being defined is one member.

• $\Pi_1^1$-CA$_0$ is an impredicative theory.
• An impredicative definition of an object refers to a presumed totality of which the object being defined is itself to be a member.
An **impredicative definition** of an object refers to a presumed totality of which the object being defined is itself to be a member.

Example: to define a set of natural numbers $X$ as

$$X = \{ n \in \mathbb{N} : \forall Y \subseteq \mathbb{N} \ F(n, Y) \}$$

is impredicative since it involves the quantified variable ‘$Y$’ ranging over arbitrary subsets of the natural numbers $\mathbb{N}$, of which the set $X$ being defined is one member.

Kripke-Platek Set Theory

- Kripke-Platek set theory, KP, is a fragment of ZFC.
- KP has no Choice, no Power Set Axiom
- Separation and Collection are restricted to formulas with bounded quantifiers
- Admissible Sets are transitive models of KP
- Admissible Ordinals: ordinals \( \alpha \) satisfying \( \mathbf{L}_\alpha \models \text{KP} \)
Kripke-Platek Set Theory

- Kripke-Platek set theory, **KP**, is a fragment of **ZFC**.
- **KP** has no Choice, no Power Set Axiom
- Separation and Collection are restricted to formulas with bounded quantifiers
- Admissible Sets are transitive models of **KP**
- Admissible Ordinals: ordinals $\alpha$ satisfying $L_\alpha \models KP$
- Gödel’s Constructible Hierarchy $L$:

\[
\begin{align*}
L_0 &= \emptyset, \\
L_\lambda &= \bigcup \{ L_\beta : \beta < \lambda \} \text{ $\lambda$ limit} \\
L_{\beta+1} &= \{ X : X \subseteq L_\beta; \ X \text{ definable over } \langle L_\beta, \in \rangle \}.
\end{align*}
\]
The **axioms** of KP are:

**Extensionality:** \( a = b \rightarrow [F(a) \leftrightarrow F(b)] \)

**Foundation:** \( \exists x G(x) \rightarrow \exists x [G(x) \land (\forall y \in x) \neg G(y)] \)

**Pair:** \( \exists x (x = \{a, b\}) \).

**Union:** \( \exists x (x = \bigcup a) \).

**Infinity:** \( \exists x \left[ x \neq \emptyset \land (\forall y \in x)(\exists z \in x)(y \in z) \right] \).

**\( \Delta_0 \) Separation:** \( \exists x (x = \{y \in a : F(y)\}) \)

\( F(y) \Delta_0\)-formula.

**\( \Delta_0 \) Collection:** \( (\forall x \in a)\exists y G(x, y) \rightarrow \exists z (\forall x \in a)(\exists y \in z) G(x, y) \)

for all \( \Delta_0 \)-formulas \( G \).

By a \( \Delta_0 \) formula we mean a formula of set theory in which all the quantifiers appear restricted, that is have one of the forms \( (\forall x \in b) \) or \( (\exists x \in b) \).
We have seen that in the case of **PA** the addition of an infinitary rule enables us to regain cut elimination.

\[\omega\text{-rule:}\]

\[
\frac{\Gamma, A(\bar{n}) \text{ for all } n}{\Gamma, \forall x A(x)}.
\]

An ordinal analysis for **PA** is then attained as follows:
We have seen that in the case of PA the addition of an infinitary rule enables us to regain cut elimination.

\(\omega\)-rule:

\[
\frac{\Gamma, A(\bar{n}) \text{ for all } n}{\Gamma, \forall x A(x)}.
\]

An ordinal analysis for PA is then attained as follows:

- Each PA-proof can be “unfolded” into a PA\(_{\omega}\)-proof of the same sequent.
We have seen that in the case of $\text{PA}$ the addition of an infinitary rule enables us to regain cut elimination.

$\omega$–rule:

$$
\Gamma, A(\bar{n}) \text{ for all } n \\
\frac{}{\Gamma, \forall x A(x)}.
$$

An ordinal analysis for $\text{PA}$ is then attained as follows:

- Each $\text{PA}$–proof can be “unfolded” into a $\text{PA}_\omega$–proof of the same sequent.
- Each such $\text{PA}_\omega$–proof can be transformed into a cut–free $\text{PA}_\omega$–proof of the same sequent of length $< \varepsilon_0$. 
In order to obtain a similar result for set theories like KP, we have to work a bit harder. Guided by the ordinal analysis of PA, we would like to invent an infinitary rule which, when added to KP, enables us to eliminate cuts.

The first ordinal analysis of KP was given by Jäger in 1978.
As opposed to the natural numbers, it is not clear how to bestow a canonical name to each element of the set–theoretic universe. Here we will use Gödel’s constructible universe $L$. The constructible universe is “made” from the ordinals. It is pretty obvious how to “name” sets in $L$ once we have names for ordinals at our disposal.
Recall that $L_\alpha$, the $\alpha$th level of Gödel's constructible hierarchy $L$, is defined by

\[
L_0 = \emptyset, \\
L_\lambda = \bigcup \{L_\beta : \beta < \lambda\} \quad \text{\(\lambda\) limit} \\
L_{\beta+1} = \{X : X \subseteq L_\beta; X \text{ definable over } \langle L_\beta, \in \rangle\}.
\]

So any element of $L$ of level $\alpha$ is definable from elements of $L$ with levels $< \alpha$ and the parameter $L_{\alpha_0}$ if $\alpha = \alpha_0 + 1$. 

FROM ARITHMETIC TO SET THEORY
Henceforth \( \Omega \) will be a name for a large ordinal or even the whole class of ordinals.
• Henceforth $\Omega$ will be a name for a large ordinal or even the whole class of ordinals.

• The problem of “naming” sets will be solved by building a formal constructible hierarchy using the ordinals $< \Omega$. 
Definition The $RS_{\Omega}$–terms and their levels are generated as follows.

1. For each $\alpha < \Omega$, $\llbracket L_\alpha \rrbracket$ is an $RS_{\Omega}$–term of level $\alpha$.

2. The formal expression

$$\{ x \in \llbracket L_\alpha \rrbracket : F(x, \bar{s}) \}_{L_\alpha}$$

is an $RS_{\Omega}$–term of level $\alpha$ if $F(a, \bar{b})$ is an $L$–formula (whose free variables are among the indicated) and $\bar{s} \equiv s_1, \ldots, s_n$ are $RS_{\Omega}$–terms with levels $< \alpha$.

$F(x, \bar{s}) \llbracket L_\alpha \rrbracket$ results from $F(x, \bar{s})$ by restricting all unbounded quantifiers to $L_\alpha$. 
Let $\mathcal{T}$ be the collection of all $RS_\Omega$-terms. For $t \in \mathcal{T}$, $|t|$ denotes the level of $t$, i.e. the maximum ordinal $\alpha$ such that $L_\alpha$ occurs in $t$.

We denote by upper case Greek letters

$$\Gamma, \Delta, \Lambda, \ldots$$

finite sets of $RS_\Omega$–formulae. The intended meaning of

$$\Gamma = \{A_1, \cdots, A_n\}$$

is the disjunction

$$A_1 \lor \cdots \lor A_n$$

$\Gamma, A$ stands for $\Gamma \cup \{A\}$ etc..
The rules of $RS_\Omega$ are:

$$(\land) \quad \frac{\Gamma, A \quad \Gamma, A'}{\Gamma, A \land A'}$$

$$(\lor) \quad \frac{\Gamma, A_i}{\Gamma, A_0 \lor A_1} \quad \text{if } i = 0 \text{ or } i = 1$$

$$(b\forall) \quad \frac{\cdots \Gamma, s \in t \rightarrow F(s) \cdots (|s| < |t|)}{\Gamma, (\forall x \in t) F(x)}$$

$$(b\exists) \quad \frac{\Gamma, s \in t \land F(s)}{\Gamma, (\exists x \in t) F(x)} \quad \text{if } |s| < |t|$$

$$(\forall) \quad \frac{\cdots \Gamma, F(s) \cdots (s \in T)}{\Gamma, (\forall x) F(x)}$$

$$(\exists) \quad \frac{\Gamma, F(s)}{\Gamma, (\exists x) F(x)} \quad \text{if } s \in T$$
\[(\notin)\quad \cdots \Gamma, s \in t \rightarrow r \neq s \cdots \cdots (|s| < |t|) \]
\[
\Gamma, r \notin t
\]

\[(\in)\quad \Gamma, s \in t \land r = s \quad \text{if } |s| < |t|
\]
\[
\Gamma, r \in t
\]

\[(\text{Cut})\quad \Gamma, A \quad \Gamma, \neg A
\]
\[
\Gamma
\]

\[(\text{Ref}_\Sigma)\quad \Gamma, A
\]
\[
\Gamma, \exists z A^z
\]

if \( A \) is a \( \Sigma \)-formula,

where a formula is said to be in \( \Sigma \) if all its unbounded quantifiers are existential.

\( A^z \) results from \( A \) by restricting all unbounded quantifiers to \( z \).
$\mathcal{H}$–controlled derivations

If we dropped the rule $(\text{Ref}_\Sigma)$ from $RS_\Omega$, the remaining calculus would enjoy full cut elimination owing to the symmetry of the pairs of rules

$$(\land) \quad (\lor)$$
$$(\forall) \quad (\exists)$$
$$(\not\in) \quad (\in)$$
However, partial cut elimination for $RS_\Omega$ can be attained by delimiting a collection of derivations of a very uniform kind. Buchholz developed a very elegant and flexible setting for describing uniformity in infinitary proofs, called operator controlled derivations.
Definition Let

\[ P(ON) = \{ X : X \text{ is a set of ordinals} \}. \]

A class function

\[ \mathcal{H} : P(ON) \rightarrow P(ON) \]

will be called operator if \( \mathcal{H} \) is a closure operator, i.e. monotone, inclusive and idempotent, and satisfies the following conditions for all \( X \in P(ON) \):

1. \( 0 \in \mathcal{H}(X) \).
2. If \( \alpha \) has Cantor normal form \( \omega^{\alpha_1} + \cdots + \omega^{\alpha_n} \), then \( \alpha \in \mathcal{H}(X) \iff \alpha_1, \ldots, \alpha_n \in \mathcal{H}(X) \).

The latter ensures that \( \mathcal{H}(X) \) will be closed under + and \( \sigma \mapsto \omega^\sigma \), and decomposition of its members into additive and multiplicative components.
For a term $s$, the operator $\mathcal{H}[s]$ is defined by

$$\mathcal{H}[s](X) = \mathcal{H}(X \cup \{ \text{all ordinals in } s \})$$
**Definition**  Let $\mathcal{H}$ be an operator and let $\Gamma$ be a finite set of $RS_{\Omega}$–formulae.

$$\mathcal{H} \models_{\rho} \Gamma$$

is defined by recursion on $\alpha$. It is always demanded that

$$\{\alpha\} \cup k(\Gamma) \subseteq \mathcal{H}(\emptyset).$$

The inductive clauses are:
\[(\exists) \quad \frac{\mathcal{H} \models_{\rho}^{\alpha_0} \Gamma, F(s)}{\mathcal{H} \models_{\rho}^{\alpha} \Gamma, \exists x F(x)} \qquad \alpha_0 < \alpha \quad |s| < \alpha\]

\[(\forall) \quad \frac{\mathcal{H}[s] \models_{\rho}^{\alpha_s} \Gamma, F(s) \text{ for all } s}{\mathcal{H} \models_{\rho}^{\alpha} \Gamma, \forall x F(x)} \qquad |s| \leq \alpha_s < \alpha\]

\[(\text{Cut}) \quad \frac{\mathcal{H} \models_{\rho}^{\alpha_0} \Gamma, B \quad \mathcal{H} \models_{\rho}^{\alpha_0} \Gamma, \neg B}{\mathcal{H} \models_{\rho}^{\alpha} \Gamma} \qquad \alpha_0 < \alpha \quad \text{rk}(B) < \rho}\]

\[(\text{Ref}_\Sigma) \quad \frac{\mathcal{H} \models_{\rho}^{\alpha_0} \Gamma, A}{\mathcal{H} \models_{\rho}^{\alpha} \Gamma, \exists z A^z} \quad \alpha_0, \Omega < \alpha \quad A \in \Sigma\]
To connect $\textbf{KP}$ with the infinitary system $\textit{RS}_\Omega$ one has to show that $\textbf{KP}$ can be embedded into $\textit{RS}_\Omega$. Indeed, the finite $\textbf{KP}$-derivations give rise to very uniform infinitary derivations.
Theorem:

If

\[ \text{KP} \vdash B(a_1, \ldots, a_r) \]

then

\[ \mathcal{H} \left| \Omega \cdot m \atop \Omega + n \right| B(s_1, \ldots, s_r) \]

holds for some \( m, n \) and all set terms \( s_1, \ldots, s_r \) and operators \( \mathcal{H} \) satisfying

\[ \{ \xi : \xi \text{ occurs in } B(\vec{s}) \} \subseteq \mathcal{H}(\emptyset). \]

\( m \) and \( n \) depend only on the KP-derivation of \( B(\vec{a}) \).
The usual cut elimination procedure works as long as the cut formulae have not been introduced by an inference $\text{Ref}_\Sigma$. As the principal formula of an inference $\text{Ref}_\Sigma$ has rank $\Omega$ one gets the following result.
Theorem: (Cut elimination I)

\[ \mathcal{H} \frac{\alpha}{\Omega+n+1} \Gamma \Rightarrow \mathcal{H} \frac{\omega_n(\alpha)}{\Omega+1} \Gamma \]

where \( \omega_0(\beta) := \beta \) and \( \omega_{k+1}(\beta) := \omega^{\omega_k}(\beta) \).
The obstacle to pushing cut elimination further is exemplified by the following scenario:

\[
\begin{align*}
\cH \models^\delta \Gamma, A \\
\cH \models^\xi \Gamma, \exists z A^z \\
\cH \models^\Omega \Gamma \quad \text{(Ref}_\Sigma) \\
\cH \models^\xi \Gamma, \forall z \neg A^z \quad \text{(\forall)} \\
\cH \models^\alpha \Omega + 1 \Gamma \quad \text{(Cut)} \\
\cH \models^\delta \Gamma, A \\
\cH [S] \models^\xi \Gamma, \neg A^s \ldots (s \in T) \quad \text{(\forall)}
\end{align*}
\]
Fortunately, it is possible to eliminate cuts in the above situation provided that the side formulae $\Gamma$ are of complexity $\Sigma$. The technique is known as “collapsing” of derivations.
In the course of "collapsing" one makes use of a simple bounding principle.

Lemma: (Boundedness)

Let $A$ be a $\Sigma$-formula, $\alpha \leq \beta < \Omega$, and $\beta \in H(\emptyset)$. If $H_{\alpha} \rho \Gamma$, then $H_{\alpha} \rho \Gamma$.
In the course of “collapsing” one makes use of a simple bounding principle.
In the course of “collapsing” one makes use of a simple bounding principle.

**Lemma: (Boundedness)**

Let $A$ be a $\Sigma$-formula, $\alpha \leq \beta < \Omega$, and $\beta \in \mathcal{H}(\emptyset)$. If

$$
\mathcal{H} \models_{\rho} \Gamma, A
$$

then

$$
\mathcal{H} \models_{\rho} \Gamma, A^{\perp, \beta}
$$
If the length of a derivation of $\Sigma$-formulae is $\geq \Omega$, then “collapsing” results in a shorter derivation, however, at the cost of a much more complicated controlling operator.
An ordinal representation system for the Bachmann-Howard ordinal

The Veblen-function $\varphi$ figures prominently in elementary proof theory. It is defined by transfinite recursion on $\alpha$ by letting $\varphi_0(\xi) := \omega^\xi$ and, for $\alpha > 0$, $\varphi_\alpha$ be the function that enumerates the class of ordinals

$$\{\gamma : \forall \xi < \alpha [\varphi_\xi(\gamma) = \gamma]\}.$$ 

We shall write $\varphi_{\alpha\beta}$ instead of $\varphi_\alpha(\beta)$.

Let $\Gamma_\alpha$ be the $\alpha^{th}$ ordinal $\rho > 0$ such that for all $\beta, \gamma < \rho$, $\varphi_\beta \gamma < \rho$.

Corollary

1. $\varphi_0 \beta = \omega^\beta$.
2. $\xi, \eta < \varphi_\alpha \beta \implies \xi + \eta < \varphi_\alpha \beta$.
3. $\xi < \zeta \implies \varphi_\alpha \xi < \varphi_\alpha \zeta$.
4. $\alpha < \beta \implies \varphi_\alpha(\varphi_\beta \xi) = \varphi_\beta \xi$. 

From arithmetic to set theory
The least ordinal ($\succ 0$) closed under the function $\varphi$ is known as $\Gamma_0$

The proof-theoretic ordinal of $\text{KP}$, however, is bigger than $\Gamma_0$ and we need another function to obtain a sufficiently large ordinal representation system.
Let $\Omega$ be a “big” ordinal. By recursion on $\alpha$ we define sets $C^\Omega(\alpha, \beta)$ and the ordinal $\psi_\Omega(\alpha)$ as follows:

\[
C^\Omega(\alpha, \beta) = \begin{cases} 
\text{closure of } \beta \cup \{0, \Omega\} \\
\text{under:} \\
+ , (\xi \mapsto \omega^\xi) \\
(\xi \mapsto \psi_\Omega(\xi))_{\xi < \alpha}
\end{cases}
\]  

(2)

\[
\psi_\Omega(\alpha) \simeq \min \{ \rho < \Omega : C^\Omega(\alpha, \rho) \cap \Omega = \rho \}.
\]  

(3)
Note that if $\psi_\Omega(\alpha)$ is defined, then

$$\psi_\Omega(\alpha) < \Omega$$

and

$$[\psi_\Omega(\alpha), \Omega) \cap C^\Omega(\alpha, \psi_\Omega(\alpha)) = \emptyset$$

thus the order-type of the ordinals below $\Omega$ which belong to the Skolem hull $C^\Omega(\alpha, \psi_\Omega(\alpha))$ is $\psi_\Omega(\alpha)$.

In more pictorial terms, $\psi_\Omega(\alpha)$ is the $\alpha^{th}$ collapse of $\Omega$. 
Lemma $\psi_\Omega(\alpha)$ is always defined; in particular $\psi_\Omega(\alpha) < \Omega$. 
Proof: The claim is actually not a definitive statement as I haven’t yet said what largeness properties $\Omega$ has to satisfy. In the proof below, we assume $\Omega := \aleph_1$, i.e. $\Omega$ is the first uncountable cardinal.

Observe first that for a limit ordinal $\lambda$,

$$C^\Omega(\alpha, \lambda) = \bigcup_{\xi < \lambda} C^\Omega(\alpha, \xi)$$

since the right hand side is easily shown to be closed under the clauses that define $C^\Omega(\alpha, \lambda)$. 

FROM ARITHMETIC TO SET THEORY
Now define

\[
\eta_0 = \sup C^\Omega(\alpha, 0) \cap \Omega \\
\eta_{n+1} = \sup C^\Omega(\alpha, \eta_n) \cap \Omega \\
\eta^* = \sup_{n<\omega} \eta_n.
\]  

(4)

Since for \( \eta < \Omega \) the cardinality of \( C^\Omega(\alpha, \eta) \) is the same as that of \( \max(\eta, \omega) \) and therefore less than \( \Omega \), the regularity of \( \Omega \) implies that \( \eta_0 < \Omega \). By repetition of this argument one obtains \( \eta_n < \Omega \), and consequently \( \eta^* < \Omega \). The definition of \( \eta^* \) then ensures

\[
C^\Omega(\alpha, \eta^*) \cap \Omega = \bigcup_n C^\Omega(\alpha, \eta_n) \cap \Omega = \eta^* < \Omega.
\]

Therefore, \( \psi_\Omega(\alpha) < \Omega \). \( \square \)
Let
\[ \varepsilon_{\Omega+1} \]
be the least ordinal \( \alpha > \Omega \) such that \( \omega^\alpha = \alpha \).

The next definition singles out a subset
\[ T(\Omega) \]
of
\[ C^\Omega(\varepsilon_{\Omega+1}, 0) \]
which gives rise to an ordinal representation system, i.e., there is an elementary ordinal representation system
\[ \langle OR, <, \hat{R}, \hat{\psi}, \ldots \rangle \]
so that
\[ \langle T(\Omega), <, R, \psi, \ldots \rangle \cong \langle OR, <, \hat{R}, \hat{\psi}, \ldots \rangle. \] (5)

“…” is supposed to indicate that more structure carries over to the ordinal representation system.
Definition $\mathcal{T}(\Omega)$ is defined inductively as follows:

1. $0, \Omega \in \mathcal{T}(\Omega)$.

2. If $\alpha_1, \ldots, \alpha_n \in \mathcal{T}(\Omega)$ and $\omega^{\alpha_1} + \cdots + \omega^{\alpha_n} > \alpha_1 \geq \ldots \geq \alpha_n$, then $\omega^{\alpha_1} + \cdots + \omega^{\alpha_n} \in \mathcal{T}(\Omega)$.

3. If $\alpha \in \mathcal{T}(\Omega)$ and $\alpha \in C^\Omega(\alpha, \psi_\Omega(\alpha))$, then $\psi_\Omega(\alpha) \in \mathcal{T}(\Omega)$. 

FROM ARITHMETIC TO SET THEORY
The side condition in the second clause is easily explained by the desire to have unique representations in \( T(\Omega) \).

The requirement

\[ \alpha \in C^\Omega(\alpha, \psi_\Omega(\alpha)) \]

in the third clause also serves the purpose of unique representations (and more) but is probably a bit harder to explain. The idea here is that from \( \psi_\Omega(\alpha) \) one should be able to retrieve the stage (namely \( \alpha \)) where it was generated. This is reflected by

\[ \alpha \in C^\Omega(\alpha, \psi_\Omega(\alpha)). \]
It can be shown that the foregoing definition of $\mathcal{T}(\Omega)$ is deterministic, that is to say every ordinal in $\mathcal{T}(\Omega)$ is generated by the inductive clauses in exactly one way. As a result, every

$$\gamma \in \mathcal{T}(\Omega)$$

has a unique representation in terms of symbols for $0, \Omega$

and function symbols for $+$, $\alpha \mapsto \omega^\alpha$, $\alpha \mapsto \psi_\Omega(\alpha)$.

The unique representation of will be referred to as the normal form.
Thus, by taking some primitive recursive (injective) coding function $[\cdots]$ on finite sequences of natural numbers, we can code $\mathcal{T}(\Omega)$ as a set of natural numbers as follows:

$$\ell(\alpha) = \begin{cases} 
[0, 0] & \text{if } \alpha = 0 \\
[1, 0] & \text{if } \alpha = \Omega \\
[2, \ell(\alpha_1), \cdots, \ell(\alpha_n)] & \text{if } \alpha = \omega^{\alpha_1} + \cdots + \omega^{\alpha_n} \\
[3, \ell(\beta), \ell(\Omega)] & \text{if } \alpha = \psi_\Omega(\beta),
\end{cases}$$

where the distinction by cases refers to the unique representation of ordinals in $\mathcal{T}(\Omega)$. With the aid of $\ell$, the ordinal representation system (5) can be defined by letting $\text{OR}$ be the image of $\ell$ and setting

$$\langle \text{OR}, \langle, \hat{R}, \hat{\psi}, \ldots \rangle$$

etc. However, a proof that this definition of

in point of fact furnishes an elementary ordinal representation system is a bit lengthy.
Theorem: (Collapsing Theorem)

Let $\Gamma$ be a set of $\Sigma$-formulae. Then we have

\[
\mathcal{H}_\eta \models^\alpha_{\Omega+1} \Gamma \quad \Rightarrow \quad \mathcal{H}_{f(\eta,\alpha)} \models^{\psi_\Omega(f(\eta,\alpha))}_{\psi_\Omega(f(\eta,\alpha))} \Gamma
\]

where $\left( \mathcal{H}_\xi \right)_{\xi \in \mathcal{T}(\Omega)}$ is a uniform sequence of ever stronger operators.
$\mathcal{H}_\delta(X) = \bigcap \{ C^\Omega(\alpha, \beta) : X \subseteq C^\Omega(\alpha, \beta) \land \delta < \alpha \}$
From the Bounding Lemma it follows that all instances of $\text{Ref}_\Sigma$ can be removed from derivations of length $< \Omega$. 
For derivations without instances of $\text{Ref}_\Sigma$ there is predicative cut-elimination.
For derivations without instances of $\text{Ref}_\Sigma$ there is predicative cut-elimination.

**Theorem: (Predicative cut elimination)**

$\mathcal{H} \vdash_\rho \Gamma$ and $\delta, \rho < \Omega \Rightarrow \mathcal{H} \vdash_0 \varphi \rho \delta \Gamma$. 
The ordinal $\psi_\Omega(\varepsilon_{\Omega+1})$ is known as the Bachmann-Howard ordinal. Combining the previous results of this section, one obtains:

**Corollary:** If $A$ is a $\Pi_2$-formula and $\text{KP} \vdash A$ then $L_{\psi_\Omega(\varepsilon_{\Omega+1})} \models A$.

The bound of this Corollary is sharp, that is, $\psi_\Omega(\varepsilon_{\Omega+1})$ is the first ordinal with that property.
We call a formula of $L \in \Delta P_0$ if all its quantifiers are of the form $\forall x \subseteq y$ or $\exists x \in y$ where $\forall$ is $\forall$ or $\exists$ and $x$ and $y$ are distinct variables. The $\Delta P_0$ formulas are the smallest class of formulae containing the atomic formulae closed under $\land$, $\lor$, $\rightarrow$, $\neg$ and the quantifiers $\forall x \in a$, $\exists x \in a$, $\forall x \subseteq a$, $\exists x \subseteq a$. $KP(P)$ has the following axioms: Extensionality, Pairing, Union, Infinity, Powerset, $\Delta P_0$-Separation and $\Delta P_0$-Collection.
We call a formula of $\mathcal{L} \in \Delta^P_0$ if all its quantifiers are of the form $Q x \subseteq y$ or $Q x \in y$ where $Q$ is $\forall$ or $\exists$ and $x$ and $y$ are distinct variables.
We call a formula of $\mathcal{L} \in \Delta_0^P$ if all its quantifiers are of the form $Q x \subseteq y$ or $Q x \in y$ where $Q$ is $\forall$ or $\exists$ and $x$ and $y$ are distinct variables.

The $\Delta_0^P$ formulas are the smallest class of formulae containing the atomic formulae closed under $\wedge$, $\vee$, $\rightarrow$, $\neg$ and the quantifiers

$$\forall x \in a, \exists x \in a, \forall x \subseteq a, \exists x \subseteq a.$$
We call a formula of $L \in \Delta_0^P$ if all its quantifiers are of the form $Q x \subseteq y$ or $Q x \in y$ where $Q$ is $\forall$ or $\exists$ and $x$ and $y$ are distinct variables.

The $\Delta_0^P$ formulas are the smallest class of formulae containing the atomic formulae closed under $\land, \lor, \rightarrow, \neg$ and the quantifiers

$$\forall x \in a, \exists x \in a, \forall x \subseteq a, \exists x \subseteq a.$$ 

$\mathsf{KP}(P)$ has the following axioms: Extensionality, Pairing, Union, Infinity, Powerset, $\Delta_0^P$-Separation and $\Delta_0^P$-Collection.
Remark.

KP(P) is not the same as KP + Powerset. The latter is a much weaker theory in which one cannot prove the existence of V_{\omega + \omega}.

Alternatively, KP(P) can be obtained from KP by adding a function symbol P for the powerset function as a primitive symbol to the language and the axiom \forall y [y \in P(x) \iff y \subseteq x] and extending the schemes of \Delta_0 Separation and Collection to the \Delta_0 formulae of this new language.

The power admissible sets are the transitive models of KP(P).
Remark.

1. $\text{KP}(\mathcal{P})$ is not the same as $\text{KP} + \text{Powerset}$. The latter is a much weaker theory in which one cannot prove the existence of $V_{\omega+\omega}$. 

2. Alternatively, $\text{KP}(\mathcal{P})$ can be obtained from $\text{KP}$ by adding a function symbol $\mathcal{P}$ for the powerset function as a primitive symbol to the language and the axiom $orall y [y \in \mathcal{P}(x) \iff y \subseteq x]$ and extending the schemes of $\Delta_0$ Separation and Collection to the $\Delta_0$ formulae of this new language.

3. The power admissible sets are the transitive models of $\text{KP}(\mathcal{P})$. 

FROM ARITHMETIC TO SET THEORY
Remark.

1. **KP(\mathcal{P})** is not the same as **KP + Powerset**. The latter is a much weaker theory in which one cannot prove the existence of \( V_{\omega + \omega} \).

2. Alternatively, **KP(\mathcal{P})** can be obtained from **KP** by adding a function symbol \( \mathcal{P} \) for the powerset function as a primitive symbol to the language and the axiom

\[
\forall y \ [y \in \mathcal{P}(x) \leftrightarrow y \subseteq x]
\]

and extending the schemes of \( \Delta_0 \) Separation and Collection to the \( \Delta_0 \) formulae of this new language.
Remark.

1. \( \text{KP}(\mathcal{P}) \) is not the same as \( \text{KP} + \text{Powerset} \). The latter is a much weaker theory in which one cannot prove the existence of \( V_{\omega+\omega} \).

2. Alternatively, \( \text{KP}(\mathcal{P}) \) can be obtained from \( \text{KP} \) by adding a function symbol \( \mathcal{P} \) for the powerset function as a primitive symbol to the language and the axiom

   \[
   \forall y [y \in \mathcal{P}(x) \leftrightarrow y \subseteq x]
   \]

   and extending the schemes of \( \Delta_0 \) Separation and Collection to the \( \Delta_0 \) formulae of this new language.

3. The **power admissible** sets are the transitive models of \( \text{KP}(\mathcal{P}) \).
The techniques used for the ordinal analysis of $\text{KP}$ can be adapted to yield the following result about $\text{KP}(\mathcal{P}) + \text{AC}$:

**Theorem** (R. 2012)
If $A$ is a $\Pi^P_2$-formula and

$$\text{KP}(\mathcal{P}) + \text{AC} \vdash A$$

then

$$V_{\psi(\epsilon_{\Omega+1})} \models A.$$  

The bound of this Corollary is sharp, that is, $\psi(\epsilon_{\Omega+1})$ is the first ordinal with that property.
Admissible sets $L_\kappa$ have the property that if $A(x, y)$ is a bounded formula, then

$$L_\kappa \models \forall x \exists y A(x, y) \Rightarrow \exists \alpha < \kappa \ L_\alpha \models \forall x \exists y A(x, y).$$
Admissible Proof Theory

Admissible Proof Theory: Cut elimination and proof collapsing techniques for infinitary proof calculi with \( \Pi_2 \)-reflection rules

Works for theories of the form:

- \( K\Pi + \text{"there are } x \text{-many admissible sets"} \)
- \( K\Pi + \text{"there are many admissible sets"} \)
- e.g., \( K\Pi_1 := K\Pi + \forall x \exists y [x \in y \land \text{"y admissible"}] \).
- \( K\Pi \equiv \Delta_1^2 - CA + BI \)
Admissible Proof Theory: Cut elimination and proof collapsing techniques for infinitary proof calculi with $\Pi_2$-reflection rules

- $\text{KP} + \text{“there are } x \text{-many admissible sets”}$
- $\text{KP} + \text{“there are many admissible sets”}$
- $\text{KPi} = \text{KP} + \forall x \exists y [x \in y \land \text{“} y \text{ is admissible”}]$.

$\text{KPi} \equiv \Delta_1^2 \text{-CA} + \text{BI}$

Beyond Admissible Proof Theory

- $\Pi^1_2$-Comprehension much stronger than $\Pi^1_1$-Comprehension and $\Delta^1_2$-Comprehension.
Beyond Admissible Proof Theory

- $\Pi_2^1$-Comprehension much stronger than $\Pi_1^1$-Comprehension and $\Delta_2^1$-Comprehension.
- $\Pi_2^1$-Comprehension cannot be described in terms of admissibility.
Beyond Admissible Proof Theory

- $\Pi^1_2$-Comprehension much stronger than $\Pi^1_1$-Comprehension and $\Delta^1_2$-Comprehension.
- $\Pi^1_2$-Comprehension cannot be described in terms of admissibility.
- $\text{KP} + \Sigma^1_1$-Separation and $(\Pi^1_2$-CA$) + \text{BI}$ prove the same sentences of second order arithmetic.
Beyond Admissible Proof Theory

- $\Pi^1_2$-Comprehension much stronger than $\Pi^1_1$-Comprehension and $\Delta^1_2$-Comprehension.
- $\Pi^1_2$-Comprehension cannot be described in terms of admissibility.
- $\mathbf{KP} + \Sigma^1_1$-Separation and $(\Pi^1_2$-$\mathbf{CA}) + \mathbf{BI}$ prove the same sentences of second order arithmetic.
- An admissible ordinal $\kappa$ is nonprojectible if there is no total $\kappa$--recursive function mapping $\kappa$--one--one into some $\beta < \kappa$, where a function $g : L_\kappa \rightarrow L_\kappa$ is called $\kappa$--recursive if it is $\Sigma^1_1$ definable in $L_\kappa$. 
Beyond Admissible Proof Theory

- $\Pi_2^1$-Comprehension much stronger than $\Pi_1^1$-Comprehension and $\Delta_2^1$-Comprehension.
- $\Pi_2^1$-Comprehension cannot be described in terms of admissibility.
- $\text{KP} + \Sigma_1$-Separation and $(\Pi_2^1\text{-CA}) + \text{BI}$ prove the same sentences of second order arithmetic.
- An admissible ordinal $\kappa$ is nonprojectible if there is no total $\kappa$-recursive function mapping $\kappa$ one-one into some $\beta < \kappa$, where a function $g : L_\kappa \rightarrow L_\kappa$ is called $\kappa$-recursive if it is $\Sigma_1$ definable in $L_\kappa$.
- $L_\kappa \models \text{KP} + \Sigma_1$-Separation iff $\kappa$ is non-projectible.
Beyond Admissible Proof Theory

- $\Pi^1_2$-Comprehension much stronger than $\Pi^1_1$-Comprehension and $\Delta^1_2$-Comprehension.
- $\Pi^1_2$-Comprehension cannot be described in terms of admissibility.
- $\textbf{KP} + \Sigma^1_1$-Separation and $(\Pi^1_2\text{-CA}) + \textbf{BI}$ prove the same sentences of second order arithmetic.
- An admissible ordinal $\kappa$ is nonprojectible if there is no total $\kappa$–recursive function mapping $\kappa$ one–one into some $\beta < \kappa$, where a function $g : L_{\kappa} \rightarrow L_{\kappa}$ is called $\kappa$–recursive if it is $\Sigma^1_1$ definable in $L_{\kappa}$.
- $L_{\kappa} \models \textbf{KP} + \Sigma^1_1$-Separation iff $\kappa$ is non-projectible.
- $\kappa$ is nonprojectible iff $L_{\kappa}$ is a limit of $\Sigma^1$–elementary substructures, i.e. for every $\beta < \kappa$ there exists $\beta < \rho < \kappa$ such that $L_{\rho} \prec_1 L_{\kappa}$.
Let $\rho < \kappa$ and $L_\rho \prec_1 L_\kappa$.
• Let \( \rho < \kappa \) and \( L_\rho \prec_1 L_\kappa \).

• Then \( \rho \) has strong reflecting properties. Suppose \( \rho + \delta < \kappa \).
\( \prec_1 \) and Reflection

- Let \( \rho < \kappa \) and \( L_\rho \prec_1 L_\kappa \).
- Then \( \rho \) has strong reflecting properties. Suppose \( \rho + \delta < \kappa \).
- If \( a_1, \ldots, a_r \in L_{\rho+\delta} \) and

\[
L_{\rho+\delta} \models A[\rho, a_1, \ldots, a_n],
\]

\[\text{FROM ARITHMETIC TO SET THEORY}\]
\begin{itemize}
  \item Let $\rho < \kappa$ and $L_{\rho} \prec_1 L_{\kappa}$.
  \item Then $\rho$ has strong reflecting properties. Suppose $\rho + \delta < \kappa$.
  \item If $a_1, \ldots, a_r \in L_{\rho + \delta}$ and
  \[ L_{\rho + \delta} \models A[\rho, a_1, \ldots, a_n], \]
  \item then there exists $\rho_0, \delta_0 < \rho$ and $b_1, \ldots, b_r \in L_{\rho_0 + \delta_0}$ such that
  \[ L_{\rho_0 + \delta_0} \models A[\rho_0, b_1, \ldots, b_n]. \]
\end{itemize}
Future Work

- Apply the machinery to “traditional" set theory.
Future Work

- Apply the machinery to “traditional” set theory.
- Simplify the Ordinal Representation Systems for $\Pi^1_2$-Comprehension
- Find new Combinatorial Principles related to Ordinal Representation System for $\Pi^1_2$-Comprehension
- Carry out ordinal analysis for $\Pi^1_n$-Comprehension for all $n$, i.e. $\mathbb{Z}_2$.
- Is $\Pi^1_2$-Comprehension the generic case?
- Conjecture: $\Pi^1_3$-Comprehension is the generic case.
